1. Introduction

1.1 Business Background

ACSE Supermarket is a supermarket chain in Lunitunia with over 40 stores and revenue of \$6 billion. In order to promote sales on a more personal level, our consulting team is tasked to investigate the strategy of personalized promotions using ACSE dataset. In this pricing adjustment project, we aim to adjust shelf prices of selected products using pricing models in order to improve revenue.

Before we dig into the ACSE data, we want to first introduce the concept of price sensitivity, which is also known as price elasticity. Price elasticity of demand is a measurement of the change in the consumption of a product in relation to a change in its price¹, and to express mathematically, it is:

$$\text{Price Elasticity} = \frac{\% \text{ Change in Quantity Demanded}}{\% \text{ Change in Price}}$$

If an item has a price elasticity less than -1, the item will be considered as elastic (very price sensitive); if an item has a price elasticity greater than -1, the item will be considered as inelastic (less price sensitive). By implementing the idea of price sensitivity, we can measure how an individual product responds to price change and also target certain products with higher price sensitivity.

Next, ACSE is investigating an everyday-low-price (EDLP) strategy, which is defined by a pricing strategy promising consumers a low price without the need to wait for sale price events or comparison shopping, and a retail store sets a low price and maintains it over a long time-horizon². It is common for products with *high* price elasticity to use EDLP strategy. Thus, in this project, our team will identify EDLP products in ACSE Supermarket and suggest strategies and actionable business plans for further personalized promotion.

1.2 Challenge

Our analytics consulting team was selected by ACSE to adjust list (shelf) prices to improve revenue. ACSE is investigating an everyday-low-price (EDLP) strategy on up to 50 products across all ACSE stores. ACSE also understands that an EDLP strategy will likely require investments in price reductions across the 50 products and would like to fund the investment with price increases on 100 less price sensitive products.

Our price change recommendations should report to ACSE the following (on a one year basis):

- a list of 150 products with recommended price changes and justifications
- expected changes in sales quantity, revenue and profitability for each store and overall across all stores

2. Data Understanding

2.1 Data Cleaning and Data Preparation

The datasets we will be using are ACSE transaction data and ACSE product data. There are 1.2 billion observations and 8 variables covering the transactions data with customer ID, store ID, and sales amount. The product table contains 155,919 observations and 10 variables, including products' categories, subcategories, and descriptions.

In order to identify products that have a significant share of the sales, we first calculated the cumulative percentage of total sales across products using transaction data, which is calculated by the cumulative revenue of each product divided by the total revenue of all products. The result will be shown in the EDA part later in the report.

2.1.1 Transaction Price

Then we select our highly demanded products, which we define as products that have a cumulative percentage of total sales less than 0.3 (products that comprise the top 30% of total sales). This will give us a total of 513 unique products. After merging back to the original transaction data, we now have 378.5 millions observations, with transaction date, prod ID, sales amount, sales quantity, and sales weight. Furthermore, we also calculate the price for each transaction: if the sales weight equals to 0, we have the price the same as sales amount; if the sales weight does not equal to 0, we have the price as the sales amount divided by sales weight. We can use this dataset to do further analysis on EDLP and pricing regression models, and below is the top five rows of our highly demanded products table:

	trans_dt	prod_id	sales_amt	sales_qty	sales_wgt	quantity	price
144687961	2018-05-12	20426078001	3.11	1	0.84	0.84	3.702381
360496369	2020-10-04	21097012001	1.79	1	0.00	1.00	1.790000
283139916	2020-01-16	20704361001	5.99	1	0.00	1.00	5.990000
231238463	2019-07-24	20049778001	3.99	1	0.00	1.00	3.990000
59632602	2018-08-19	20007535001	2.09	1	0.19	0.19	11.000000

Figure 1: Highly demanded products table

2.1.2 Converting to Weekly Basis

Next, we notice that the transaction data is on a daily basis, whereas for most of the products, they do not have transaction data everyday. In order to smooth out the noise in the date feature, we decided to transform the transaction date from daily basis to weekly basis. In this way, we can compute the price elasticity for each individual product each week, and we can also use the weekly data to set our uncontrollable factors (such as seasonality) in our later response function.

2.1.3 List Price, Discounted Price, and Demand

Besides the dates, there are some other features we create that relate to discount price, list price, and demand:

- **list_price**: highest price (which we calculated from sales quantity and sales amount) for each product
- **weekly_demand**: sum of weekly's quantity for each product
- **discounted_price**: weekly total revenue divided by weekly_demand (weekly total quantity) for each product
- **weekly_amount**: weekly revenue for each product (discounted_price * weekly_demand)
- **discounted_price_pct**: the percentage change in discounted price comparing to previous time period for each product
- **weekly_demand_pct**: the percentage change in demand comparing to previous time period for each product
- **discount_level**: the percentage change in discounted price comparing to list_price, calculated by $(\text{list_price} - \text{discounted_price}) / \text{list_price}$

2.1.4 Complement Price, Substitute Price, and Competitor Price

The price of complements and substitutes are also important for price response function. Here, we use cross-price elasticity to identify if a product is complement or substitute to another product, the cross-price elasticity function is as below:

$$\text{Cross Price Elasticity of Demand} = \frac{\% \text{Change in Quantity Demanded for Good A}}{\% \text{Change in Price of Good B}}$$

If the value of cross-price elasticity is negative, then good A and good B are complements, since an increase in demand for A is accompanied by an increase in the quantity demanded of B. In contrast, good A and good B are substitutes when the value of cross-price elasticity is positive, since price increases of A cause a rise in demand for B.³

Aligned with the aforementioned definitions of complements and substitutes, we firstly create a new table of all the possible product pairs, and then we calculate the cross-price elasticity for each product on a weekly basis. A sample table of paired products with their cross-price elasticity is shown below. If the cross-price elasticity is greater than 1, we consider those products as substitutes, and we average the discounted price for all the substitutes as the substitute price of the target product. If the cross-price elasticity is less than 1, we consider those products as complements, and we also average the discounted price for all the complements as the complement price of the target product.

³“Other Demand Elasticities”, courses.lumenlearning.com/boundless-economics/chapter/other-demand-elasticities/

	prod_id_x	YearWeek	weekly_demand_pct	prod_id_y	discounted_price_pct	discounted_price	cross_elasticity
41408168	21204739	2020-20	0.915792	21090447001	-0.014587	6.08	-62.782623
41408169	21204739	2020-20	0.915792	21092325001	0.028609	7.91	32.011090

41408177	21204739	2020-20	0.915792	21179969001	0.016293	4.99	56.206728

Figure 2: Cross elasticity table

After computing the complement price and substitute price, our next step is to calculate competitor price. Since we can regard substitutes as competitors for a product, we identify a product's competitor as the one with the largest value of cross-price elasticity. In order to calculate competitor price for each product, we use the discounted price of the product with the largest cross elasticity as the competitor price of the target product.

2.1.5 Seasonality

In terms of seasonality, we notice that our data already included the week index, which can also be used to measure the different time period, and it is even more precise than using seasons. Thus, we decide to use the week number in each year as a "seasonality" measure.

The final complete table after data cleaning and data preparation is shown below:

	prod_id	YearWeek	list_price	weekly_amt	weekly_demand	discounted_price	year	week	discounted_price_pct	weekly_demand_pct
0	20001892	2017-25	5.0	2235.0	447	5.0	2017	25	NaN	NaN
1	20001892	2017-26	5.0	8785.0	1757	5.0	2017	26	0.0	2.930649
2	20001892	2017-27	5.0	9285.0	1857	5.0	2017	27	0.0	0.056915
3	20001892	2017-28	5.0	11690.0	2338	5.0	2017	28	0.0	0.259020
4	20001892	2017-29	5.0	10430.0	2086	5.0	2017	29	0.0	-0.107784

discount_level	substitute_price	complement_price	competitor_price
0.0	NaN	NaN	NaN
0.0	7.261495	8.565272	15.28
0.0	44.256554	7.445517	15.77
0.0	7.942552	38.590053	9.81
0.0	17.812929	8.369198	11.88

Figure 3: Weekly level data with cross elasticity table

2.2 Exploratory Data Analysis

2.2.1 Cumulative Percentage of Total Sales

There are always products in ACSE Supermarkets that customers frequently purchase, which will result in a long tail across items when focusing on cumulative percentage of store sales. The top

12.95% of items account for 90% total sales, and the lowest selling 80.78% of items account for only 5% of total sales.

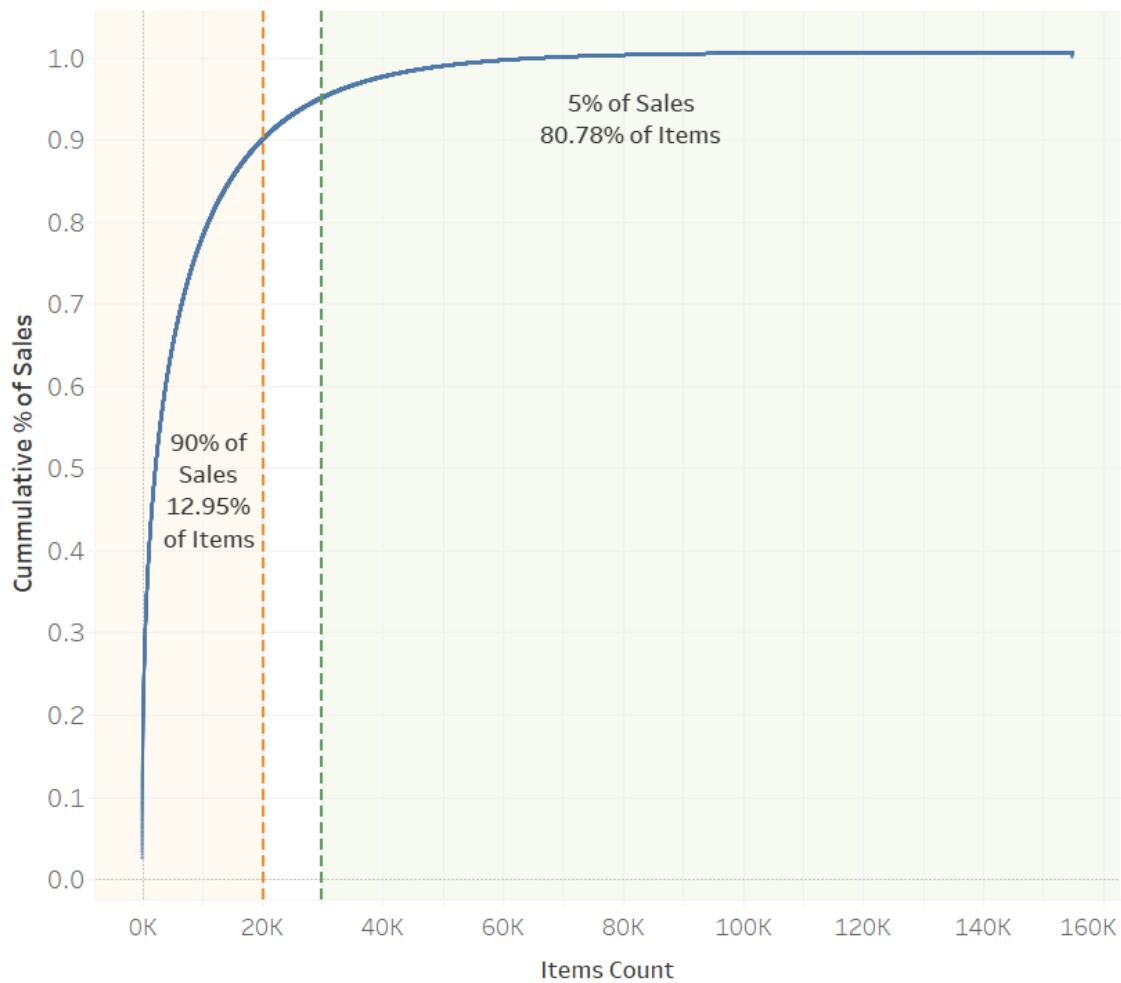

Figure 4: Cumulative percentage of total sales across items

2.2.2 Markdowns

The distribution of the average markdown percent on products ranges from 0 to 89.35%; only 8 products of the 511 had an average markdown percentage over 50%. Understanding markdown percentage levels for individual products is important as customers may recognize if a typically highly marked down product is seeing price increases.

Products with an Average Markdown Percentage Over 50%

2.2.3 Prices of Substitute/Competitor Products

As demonstrated in the price comparison graph below, on average, target products' substitute/complement products tend to be of a higher price. The median difference in the list price of a target product and the competitor products price is a -2.2, suggesting that list prices of most target products can be decreased without customers switching over to the substitute products.

List Price vs Competitor Price

Figure 5: List Price vs. Competitor Price

3. Price Response Function

3.1 Logit Response Function

The causal factors for us to consider in the price response model include price factors (e.g. product discount level, price for substitute/complement products) and untrollable factors (e.g. seasonality). The previous data cleaning and data preparation parts give us most of the factors for modeling.

When optimal prices are needed, the logit response function should be used for this purpose. Before modeling, we transformed the demand by logistic transformation. The demand_transformed is calculated from weekly_demand_max (the maximum weekly demand) for each product as the theoretical maximum demand of this product in any period, using:

$$demand_transformed = \log\left(\frac{weekly_demand}{weekly_demand_max - weekly_demand}\right)$$

After the logistic transformation on the historical demand, we kept other factors with no transformations and defined our Price Response Function as:

$$\text{demand_transformed} \sim \text{discounted_price} + \text{substitute_price} + \text{complement_price} + \text{week} + \text{discount_level}$$

The following table shows the result from our Price Response Function, with *prod* as the product ID, and *coef0* to *coef4* as the coefficient of each variable:

	prod	coef0	coef1	coef2	coef3	coef4	intercept
0	20001892	0.000000	0.004537	0.006521	0.000013	0.000000	-0.953165

Figure 6: Price Response Function Result

3.2 Obtaining the Optimal Price

The price response function can give us a linear relationship between $\log(\text{demand})$ and selected variables. In order to investigate EDLP products and less price sensitive products, further work needs to be done to find the optimal price for each product. Theoretically, If we want to adjust list prices to maximize revenue (and ignore incremental cost), and to express it in an equation, it is:

$$\max_p pd(p)$$

The equation can be solved by taking the derivative of $M(p)$ and setting it equal to 0:

$$M'(p) = pd'(p) + d(p) = d(p)\left(\frac{pd'(p)}{d(p)} + 1\right) = d(p)(\epsilon(p) + 1) = 0$$

Therefore, from the above equation, we can see that the revenue-maximizing price p can be derived when price elasticity ($\epsilon(p)$) equals to -1.

For a logit price response function, the formula of price elasticity is:

$$\epsilon(p) = \frac{bp}{1 + e^{-(a+bp)}}$$

It is worth noting that $(a+bp)$ can be obtained from the result in the previous step, where we use the five coefficients and the intercept as the exponent of e . Specifically, a is the intercept, b is the coefficient of `discounted_price`, and we add c , d , e , and f as the coefficients of the rest of the variables.

Instead of directly calculating the optimal p when the elasticity of p equals to -1 , we iterated multiple numbers of price as p to calculate the elasticity for each product, and then used the price which makes the elasticity equal to (or extremely close to) -1 .

	prod_id	price	elasticity	dist
407	20005858	7.07	-0.984984	0.015016

Figure 8: Optimal price and discounted price

Using the above table, we can distinguish the 50 EDLP products and 100 less price sensitive products as our price change recommendations for ACSE. The detailed product list and explanation is demonstrated in the following part of the report.

4. Price Recommendation

4.1 Products List

Using the analysis and modeling techniques described above, our team identified 50 products that can withstand a price decrease to become EDLP items and 100 items whose prices can be increased to offset the costs. We selected these 150 products out of 234 promising products (all 234 products' predicted elasticity deviates from -1 with 0.15) whose predicted revenue is as high as possible. The product list contains important features of the product, current prices, suggested price, elasticity, the percent increase in price, and the additional revenue it will bring in.

4.1.1 Price Decrease Products

The following 50 products have been identified to be in the ELDP category. The product list below for these products is sorted by ascending additional revenue provided. The range of the price percent changes is from -2% to -84%.

ELDP: Products to Target for Price Decreases							
Product ID	Current List Price	Current Discounted Price	Suggested Price	Product Elasticity	Distribution	Percent Price Decrease	Revenue
20801192	16.56491713	14.48767956	14.14	-0.96516019	0.03483981	-2%	14390.52

Figure 9: Product to target for price decrease

4.1.2 Price Increase Products

The following products have been identified to see price increases in order to fund the ELDP initiative; this list has been sorted in ascending order for additional revenue provided. This selected range of products sees an increase in price from .28% to 1731%.

Products to Target for Price Increases

Figure 10: Product to target for price increase

4.2 Executing Price Changes

A few nuances have to be considered when thinking about executing the price changes mentioned above. Because consumers are very likely to notice large increases in price, our team suggests performing further research on the specific time periods and levels of price increases that should take place for products with over 60% suggested price increases.

Additionally, research suggests that customers should be made aware of the reasons for price increases⁴. It might play to ACSE's benefit to add little tags next to prices with significant increases that explain that these increases are offsetting price decreases in other products. In line with the Harvard article, messaging surrounding price changes should focus on the benefits ACSE's consumers will receive as a result of the EDLP.

5. Expected Changes

After we calculated the optimal price and found the price response function for each product, we used the following function to calculate the demand based on the optimal price:

$$d(p) = \frac{Ce^{-(a+bp)}}{1+e^{-(a+bp)}}$$

Since the dependent variable of the price response function is the demand with logistic transformation, we transformed the result of demands back as the expected demand with the price adjustment. By multiplying the demand and price, we obtained the maximized revenue for each product as the expected revenue. The table below shows the expected changes in demand and revenue.

	prod_id	price	demand	revenue
0	20005858	7.07	454.782106	3215.31
1	20035921	7.07	2194.195434	15512.96

Figure 11: Expected changes in demand and revenue

⁴ "If You're Going to Raise Prices, Tell Customers Why", hbr.org/2021/06/if-youre-going-to-raise-prices-tell-customers-why

Using the transaction data, we can also calculate the yearly revenue of the products that would have price adjustment in each store. Compared to the yearly revenue of products with price adjustments, we found that the revenue in all the stores would increase, with the maximum increase of 92% in store 1424, and an increase of 51.53% across all stores. The table below shows the top ranked stores by the percentage of revenue increase.

store_id	original_profit	optimal_profit	profit_increase	original_revenue	optimal_revenue	revenue_increase	revenue_increase_pct

Figure 13: Top stores ranked by % increase in demand

6. Conclusion

Our team's analysis into ACSE Supermarket's product pricing recommendation has resulted in product promotion strategies to increase store revenue. Implementing price elasticity and logit response function provide an extra layer of personalization that will directly speak to products and customers. Our team strongly believes in these recommendations and looks forward to helping with their implementation in the future.
